White House Area Transportation Study

3

White House Area Closures

12/19/07

White House Area Transportation Study

4

Key Transportation Impacts

- Washington D.C. has a resilient / adaptable transportation system that accommodated the closures by:
 - Inconveniencing travelers with additional travel times of up to 12 minutes per trip
 - Spreading travel over a broader geographic area
 - Exposing neighborhoods to increased pass-by traffic
 - Discouraging people from traveling in downtown

12/19/07

5

Local Connectivity

12/19/07

White House Area Transportation Study

6

Regional Connectivity

12/19/07

White House Area Transportation Study

7

Modeling Requirements

- Estimate impacts of major new facilities and minor traffic operational improvements
- Track individuals directly affected and how each alternative mitigates these impacts
- Generate statistics for all of downtown, all modes, and all times of day
- Account for time of day changes in network capacity and operations
 - traffic signals, street parking, turn restrictions, vehicle use restrictions, reversible roadways, and transit services
- Prepare for NEPA through consistency with the MWCOC model and CLRP improvements

White House Area Transportation Study

8

Modeling Approach

12/19/07

White House Area Transportation Study

9

Selected Approach

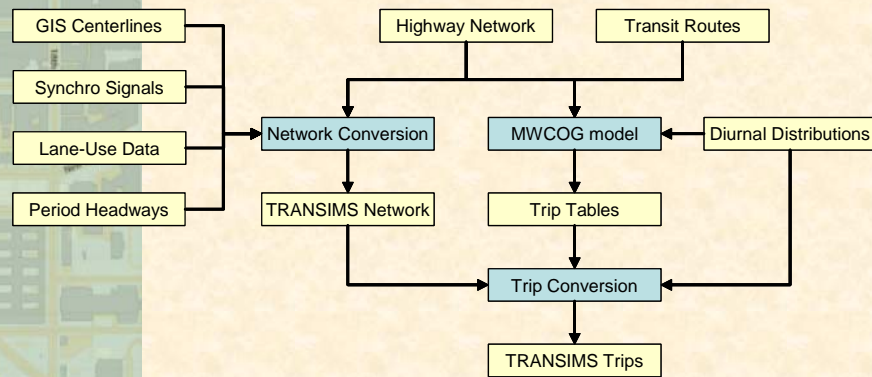

- Integrate the MWCOC regional model with a planning level simulation of the traffic and transit operations in a detailed subarea covering much of Washington D.C. and Arlington CBD
 - MWCOC trip tables and network → TRANSIMS regional routing and subarea simulation

Assignment Process

12/19/07

White House Area Transportation Study

14

Key Features of the Approach

- Directly considers MWCOG and CLRP changes
- Large simulation area enables travel path changes and the evaluation of secondary impacts
- Regional routing with subarea simulation adjusts thru traffic and trip entry/exit points
- The planning level simulation combines detailed traffic operations by time of day in the study area with synthetic controls outside of the study area
- Tracks individuals for direct comparisons of impacts and market segments between alternatives
- Includes effective visualization and analysis tools

12/19/07

White House Area Transportation Study

15

Limitations of the Approach

- The linkage between the MWCOG model and the TRANSIMS simulation is one way
 - The trip tables are fixed – no feedback to mode choice
- Vehicle movements are limited to fixed length cells allocated to each lane of each link
 - The speed at any given second is limited to: 0.0, 13.4, 26.9, 40.3, 53.8, 67.2, or 80.6 miles per hour.
- A model application that requires 100 iterations to achieve convergence takes about 12.5 days to complete
- The overall quality of the validation would benefit from better and more consistent traffic counts

12/19/07

16

Technical Challenges

12/19/07

White House Area Transportation Study

17

Simulation Dynamics

- “Standards” vs. Downtown
 - Smaller cell sizes to increase density
 - More random slow down and reaction time to reduce speeds
 - Less permissive lane changing in queues
- Freeways vs. Arterials
 - Originally over-estimated freeways and under-estimated arterials
 - Calibrated freeways and arterials separately

12/19/07

White House Area Transportation Study

18

Validation Targets

- 15-minute traffic counts are needed for trip table adjustments and model validation
 - Not generally available or reliable
- Multiple count sources, years, seasons, and time periods are difficult to reconcile
 - Considered count reliability in validation weights
- Day-to-day traffic counts vary by 10-12%
 - Seasonal variations are much higher
 - Resiliency tests were used to quantify the impacts of demand changes on alternative performance

21

Equilibrium/Convergence

- Single path trips are realistic, but sub-optimal
 - User-equilibrium convergence is approximated
- Simulated link and turning movement delays are very sensitive to small changes in traffic
 - Stabilized by successive averaging
 - Keep the changes/iteration small
- Regional-subarea interactions need reasonably stable simulation inputs
 - Fixed subarea demand improves convergence
 - Multiple subarea iterations per regional iteration

12/19/07

White House Area Transportation Study

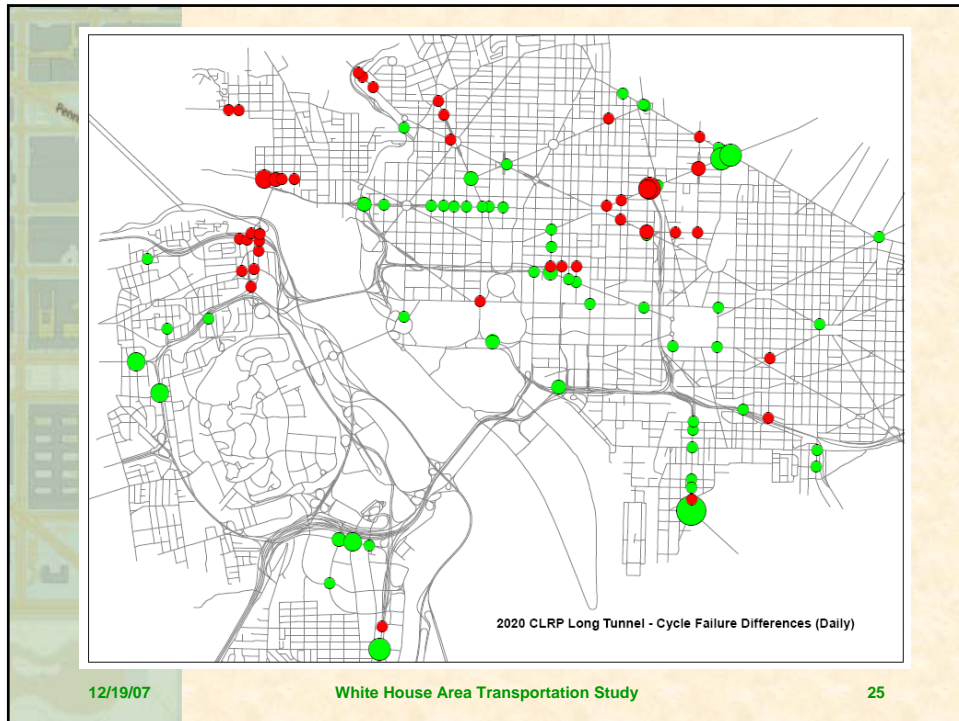

22

Optimizing Traffic Controls

- Existing traffic controls are sub-optimal from a thru-put perspective
 - Pro-transit and pro-neighborhood policies
- Since each future alternative impacts existing traffic controls...
 - How should the system be optimized to accommodate the alternative?
 - How much of the system should be adjusted (e.g., how far away)?

12/19/07 White House Area Transportation Study 24

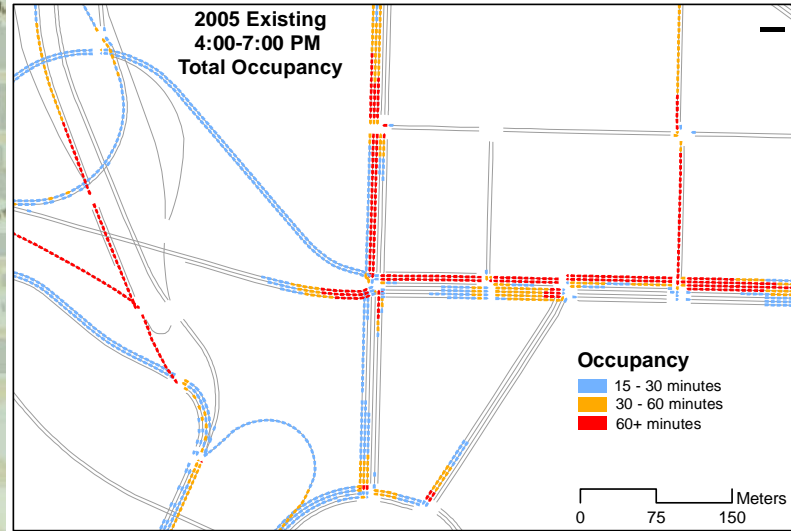

Comparing Alternatives

- Aggregate statistics are often misleading
 - Difficult to distinguish performance impacts from total traffic differences
 - Winners and losers average to small impacts
 - Large impacts are lost among the majority of trips with small impacts
- Comparing dynamic data is difficult
 - Hard to compare and evaluate visualizations
 - Static snapshot images are rarely representative
 - Aggregate views of vehicle movements present congestion more effectively
